The aim of treatment for leptomeningeal metastases is to control the growth of the cancer and relieve symptoms. Treatment might be able to control the cancer cells in the meninges for some months, or possibly more than a year with the newer targeted agents for treatment of certain types of lung cancer.

The treatment of leptomeningeal metastases depends on many factors, including severity of symptoms, type of primary cancer, the person's general health, presence of other metastases, and more. It's important to note that, while treatment may inhibit the progression of neurological symptoms, those that are present at the time of diagnosis often persist.

**Leptomeningeal Metastases: Symptoms, Diagnosis, and More**

The goal of treatment of leptomeningeal metastasis is to improve survival and to maintain quality of life by delaying neurological deterioration. Tumour-specific therapeutic options include intrathecal pharmacotherapy, systemic pharmacotherapy and focal radiotherapy. Recently, improvement of leptomeningeal disease-related progression-free survival by adding intrathecal liposomal cytarabine to systemic treatment versus systemic treatment alone has been observed in a randomised phase III ...

While chemotherapy and radiotherapy are mildly effective forms of treatment, molecularly targeted therapies and immunotherapy have shown antitumour activity for brain metastases and are promising treatment options, although information on their activity in leptomeningeal metastasis is scarce.

Leptomeningeal metastasis is an uncommon and typically late complication of cancer with a poor prognosis and limited treatment options. Diagnosis is often challenging, with nonspecific presenting symptoms ranging from headache and confusion to focal neurologic deficits, such as cranial nerve palsies. Standard diagnostic evaluation involves a neurologic examination, magnetic resonance imaging of the brain and spine with gadolinium, and cytologic evaluation of the cerebral spinal fluid.

Current treatments for leptomeningeal tumors are palliative. The goals for treatment include prolonging survival and stabilizing neurological symptoms. A combination of surgery, radiation, and chemotherapy treatment can be used to help improve the prognosis of the disease.

**Leptomeningeal cancer - Wikipedia**

As therapeutic options and supportive care for the treatment of neoplastic disease have improved, there has been an associated increase in the incidence of leptomeningeal disease. The therapeutic efficacy of ionizing radiation, systemic agents, and intrathecal drugs will be examined from the existing literature.

While there's no cure for leptomeningeal disease yet, radiation and chemotherapy are the two most common treatments. Since it's very hard for drugs to make it into the central nervous system, the chemotherapy is delivered intrathecally. That means we drill a small hole in the skull and insert a port, which is used to deliver the drug.
