In order to gain further insight into the nature of elevated pressure as a stress, the response of *Escherichia coli* to pressure has been examined. Many DNA-binding proteins display pressure-sensitive binding properties, and in many instances, this is due to hydration effects.

Microbial adaptation is the term used to describe the ability of microbes to endure the selective pressures of their environment. For microbial pathogens, these pressures may be due to the biological hurdles of the body and the tissues that they invade to establish infection 1 or the immune, antiseptics, or pharmaceutical control measures that we throw at them.

The microbial communities that have evolved within these high-altitude aquatic ecosystems must tolerate chemical and physical stresses such as wide fluctuations in daily temperatures, hypersalinity, and variable pH and be adapted to high levels of UV radiation, a low level of nutrient availability, and high concentrations of heavy metals, especially arsenic (13, 14, 18, 19, 99).

Cross-stress adaptation, a phenomenon that a given stress confers a fitness advantage (or disadvantage) to other unrelated stresses, has been observed in many organisms across the tree of life, ranging from microbes to plants and humans (Boussiba et al., 1975; Dragosits et al., 2013; Chauhan et al., 2015; Zorraquino et al., 2016). In the past three decades, researchers reported many special genes responding to a certain stress; however, more and more studies found that these responding genes ...
